Abstract

The news subheading summarizes an article's contents in several sentences to support the headline limited to solely conveying the main contents. So, it is necessary to generate compelling news subheadings in consideration of the structural characteristics of the news. In this paper, we propose a subheading generation model using topical headline information. We introduce a discriminative learning method that utilizes the prediction result of masked headline tokens. Experiments show that the proposed model is effective and outperforms the comparative models on three news datasets written in two languages. We also show that our model performs robustly on a small dataset and various masking ratios. Qualitative analysis and human evaluations also show that the overall quality of generated subheadings improved over the comparative models.

1 Introduction

The news headline summarizes the article to grab the attention and interest of the readers (Dor, 2003; Hantidou, 2009; Ecker et al., 2014). However, the headline is written in a brief form of short sentences with topic-related phrases (Yamada et al., 2021), making it hard for users to grasp the entire content of the news article from the headline alone. To tackle this problem, some news vendors pro-

vide the topical knowledge from the body of the article. The main approach is to add auxiliary signals to make the model aware of topical knowledge. Dou et al. (2021) and Aralikkatt et al. (2021) add an external guidance signal by lexical similarity between input text and summary. Yamada et al. (2021) extracts the context word sequences from the reference to reflect some important phrases from the article. Although these external auxiliary sources provide diverse topical signals, they are cost-intensive to heuristically manipulate and have limitations in guiding the overall topical information of the article. Other approaches incorporate contrastive learning into sequence-to-sequence (seq2seq) model, allowing the model to learn topical representation of the input text (Lee et al., 2021; Liu et al., 2021; Wu et al., 2020). They explicitly constructs positive or negative inputs to introduce contrastive loss as an augmentation of MLE training.

In this work, we propose a novel framework for generating compelling news subheadings by discriminating whether each token in the reconstructed headline is the same as the token in the original headline. Unlike previous approaches that use heuristically extracted topical information or positive and negative pairs, we utilize *headline* that fundamentally implies the topic of the entire article. We make full use of this indispensable object as

New insights about *Quercus faginea* (s.l.) taxonomic status in northern Africa
Abdeljalil Aissi

Received: 11 July 2022 / Accepted: 5 May 2023 / Published online: 12 June 2023

Abstract. The genus *Quercus* is known for its taxonomic complexity that is characterized by the abundant morphological diversity and phenomena of hybridization and introgression found in a number of its species. The number of taxa continues to change and evolve despite systematists' attempts to clarify and simplify it. The *Quercus faginea* s.l. complex represents one of the most conclusive and complex examples found in the North-Western Mediterranean and North Africa. Nevertheless, the systematics of this complex have undergone a remarkable evolution from the first Lamarkian taxa *Q. lusitanica* and *Q. faginea* to the present day, especially in the Iberian Peninsula, Tunisia, and Algeria, by virtue of the recognized taxa. To compare Moroccan taxa with those found in other regions, as well as update the taxonomic status of populations found in Morocco, data found in a corresponding bibliography was used for a critical and objective analysis. Although the taxonomic situation remains unresolved, the analysis found that there is a likely presence of the *faginea* variety in Morocco, while also anticipating the confirmation of a new morphological analysis that accounts for the stable criteria used for an infraspecific distinction. The rest of Morocco's stands seem to be represented by *Q. canariensis* and *Q. faginea* subsp. *brateroi*. Considering the uncertain existence of *maroccana*, further study of its distinct morphological and biogeographical peculiarity is required.

Keywords: morphological traits, infraspecific distinction, biogeographic peculiarity, *Q. faginea* subsp. *brateroi* f. *maroccana* (Braun-Blanquet & Maire) Villar.

Introduction

Q. faginea (Schwarz, 1964), before they were included in *Q. lusitanica* and *Q. pubescens* Willd., respectively. The classification of this complex, otherwise known as *Q. lusitanica* (s.l.) (whose forms of the species sensu lato were included under *Q. lusitanica*) or *Q. faginea-mirbeckii* Villar, has continuously raised many problems since Lamark (1783) described his *Q. faginea* Lam. as a different species from his *Q. lusitanica* Lam. (cf. Vázquez *et al.*, 2018; Aissi *et al.*, 2021). Despite this, there is a tendency towards simplification, especially in the Iberian Peninsula, since the separation of the two species *faginea* and *canariensis* (incl. *Q. lusitanica* var. *salmontiana* Webb; *Q. salmuntiana* (Webb) Cout., Amaral Franco 1990, Vázquez *et al.*, 2018) by Schwarz (1964), and the subdivision of *Q. faginea* into two subspecies (*faginea* & *brateroi*) by Amaral Franco (1990).

A key example is *Q. faginea* Lam. (s.l.), a complex of Ibero-Maghrebian species (Iberian Peninsula, Morocco, Algeria, and Tunisia) which includes different forms and species; *Q. faginea* Lam. (s.s.), *Q. canariensis*

Abstract: The valid deciduous *Quercus* L. species from North Africa have been largely discussed by many authors. The current species remain yet uncertain. In this study, we compare several populations of presumably *Q. canariensis* Willd. and *Q. faginea* Lam. from Algeria with pure populations of these species from the northeast of the Iberian Peninsula. Different morphological characters from leaves have been analyzed. Principal components analysis and a canonical analysis of principal coordinates have been used to observe the relationship between samples, groups and the seven quantitative variables. Distances among centroids have been reported and a SIMPER procedure has also been executed to better explain the different variability within and between groups. PERMANOVA has been applied to test for significant differences between the groups. For the trichomes study, ANOVA models have been used. From our analysis, we conclude that in Algeria, we have a single *Q. canariensis* Willd. population, different from the Iberian population we examined. It probably corresponds morphologically to *Q. mirbeckii* Durier, currently considered a synonymy of *Q. canariensis* Willd., and for the "*Q. faginea*" group we have two Algerian populations: *Q. faginea* Lam. subsp. *faginea*, found in the northeast Iberian Peninsula, and *Q. ilemicensis* (A.D.C.) Maire and Weiller ex Greuter and Burdet. Previous results from other authors have also been discussed.

Keywords: morphometry; *Quercus*; *Q. faginea*; *Q. canariensis*; Algeria; Catalonia

1. Introduction

Quercus L. (Fagaceae) is widely distributed throughout the Northern Hemisphere, both in the Holarctic (Nearctic and Palearctic), the Neotropics (with the southern limit found in Colombia, where a single species, *Q. laubmohtii* Boenpl., is known), and some parts of the Oriental region, almost overlapping the Fagaceae distribution [1]. Currently, it includes more than 400 species, although less conservative authors suggest there could be more than 500 or 600 [2,3]. The current consensus [4] shows that *Quercus* is divided into two subgenera: *Quercus* and *Cerris*. The subgenus *Quercus* is divided into five sections (*Protobalanus*, *Ponticae*, *Virentes*, *Lobatae*, and *Quercus*) and the subgenus *Cerris* includes three sections (*Cyclobalanus*, *Ilex*, and *Cerris*). The genus *Quercus* L. (Fagaceae) is known for its complexity, and the difficulty that taxonomists face in classifying the taxa they

How to cite: Aissi, A., 2023. New insights about *Quercus faginea* (s.l.) taxonomic status in northern Africa. *Mediterr. Bot.* 44, e82996. <https://doi.org/10.5209/mbot.82996>

Introduction

The genus *Quercus* constitutes one of the most important and diverse components of the forest ecosystems of southwestern Europe and North Africa (Bussotti & Grossoni, 1998; Gil-Pelegrin *et al.*, 2017; Vila-Vieira *et al.*, 2023). It has long been associated with great controversy, linked to the considerable genetic richness and intra- and interspecific hybridization, reflected in the high morphological variability disclosed by its taxa, as well as the numerous intermediate forms that result (Denk *et al.*, 2017 and references therein). The number of taxa is still debated among botanists, as the definition of the biological concept of a *Quercus* species is still unclear due to hybridization between different taxa and species, in particular (Burger, 1975; Vila-Vieira *et al.*, 2022). A key example is *Q. faginea* Lam. (s.l.), a complex of Ibero-Maghrebian species (Iberian Peninsula, Morocco, Algeria, and Tunisia) which includes different forms and species; *Q. faginea* Lam. (s.s.), *Q. canariensis* *Q. faginea* (Schwarz, 1964), before they were included in *Q. lusitanica* and *Q. pubescens* Willd., respectively. The classification of this complex, otherwise known as *Q. lusitanica* (s.l.) (whose forms of the species sensu lato were included under *Q. lusitanica*) or *Q. faginea-mirbeckii* Villar, has continuously raised many problems since Lamarck (1783) described his *Q. faginea* Lam. as a different species from his *Q. lusitanica* Lam. (cf. Vázquez *et al.*, 2018; Aissi *et al.*, 2021). Despite this, there is a tendency towards simplification, especially in the Iberian Peninsula, since the separation of the two species *faginea* and *canariensis* (incl. *Q. lusitanica* var. *salzmaniana* Webb; *Q. salzmaniana* (Webb) Cent., Amal Franco 1990; Vázquez *et al.*, 2018) by Schwarz (1964), and the subdivision of *Q. faginea* into two subspecies (*faginea* & *broteri*) by Amal Franco (1990). The same status is in force in Algeria since the recent taxonomic study (Aissi *et al.*, 2021). On the latter, representative samples of the country's stands were selected and morphological analysis was carried out.

Bark anatomy and cell size variation in *Quercus faginea*

Teresa QUILHÓ^{1,2}, Vieslma SOUSA¹, Fatima TAVARES¹, Helena PEREIRA¹

¹Centre of Forests and Forest Products, Tropical Research Institute, Tapada da Ajuda, 1347-017 Lisbon, Portugal
²Centre of Forestry Research, School of Agronomy, Technical University of Lisbon, Tapada da Ajuda, 1349-017 Lisbon, Portugal

Received: 30.01.2012 • Accepted: 27.09.2012 • Published Online: 15.05.2013 • Printed: 30.05.2013

Abstract. The bark structure of *Quercus faginea* Lam. in trees 30-60 years old grown in Portugal is described. The rhytidome consists of 3-5 sequential periderms alternating with secondary phloem. The phelloderm is composed of 2-5 layers of cells with thin suberized walls and narrow (1-3 seriate) tangential band of lignified thick-walled cells. The phelloderm is thin (2-3 seriate). Secondary phloem is formed by a few tangential bands of fibres alternating with bands of sieve elements and axial parenchyma. Formation of conspicuous sclerids and the dilatation growth (proliferation and enlargement of parenchyma cells) affect the bark structure. Fused phloem rays give rise to broad rays. Crystals and druses were mostly seen in dilated axial parenchyma cells. Bark thickness, sieve tube element length, and secondary phloem fibre wall thickness decreased with tree height. The sieve tube width did not follow any regular trend. In general, the fibre length had a small increase toward breast height, followed by a decrease towards the top. Fibre width decreased with height in most of the cases, but in some trees a slight increase was noticed at the top.

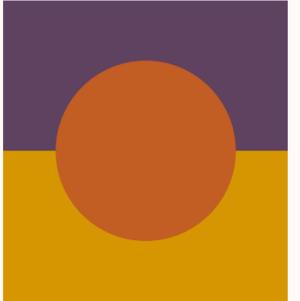

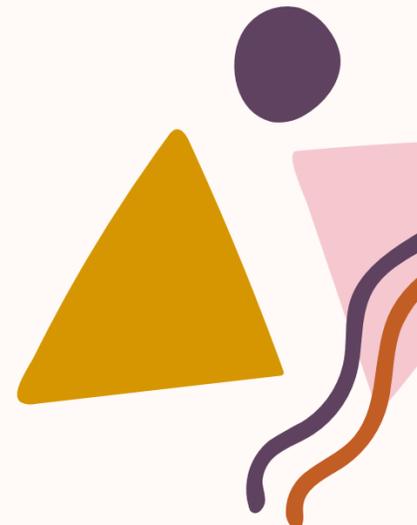

Key words: *Quercus*, bark, anatomy, fibre, sieve tube elements

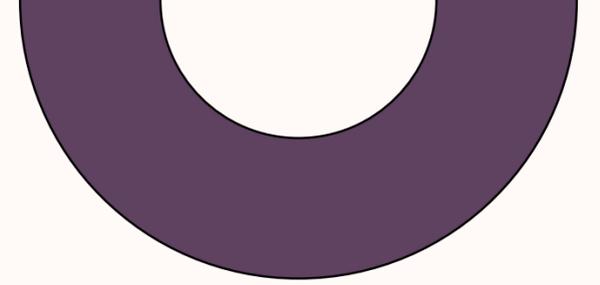

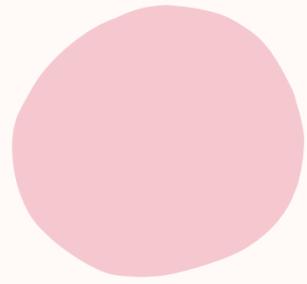

1. Introduction

The Portuguese oak (*Quercus faginea* Lam.) is a species native to the western Iberian Peninsula and the North African countries of Morocco, Tunisia, and Algeria. The species grows well in the temperature range of 15-25 °C in the summer and from -4 to 8 °C in the winter, with annual precipitation between 350 and 2000 mm (Oliveira *et al.*, 2001). It is a medium-sized deciduous or semideciduous tree growing to a height of 20 m and a diameter of 80 cm. In Portugal, *Quercus faginea* coexists with other oak species such as *Quercus ilex* L., *Quercus suber* L., *Quercus pyrenaica* Willd., and *Quercus robur* L. The distribution has become fragmented in the last centuries (Gabilho & Silva, 1996), and there are concerns on future area reduction with warming and reduced rainfall trends, since drought is the main limiting factor of sub-Mediterranean oaks (Cotillas *et al.*, 2009), specifically for *Q. faginea* (Corcuera *et al.*, 2004; Montserrat-Martí, 2009). Studies on bark anatomy are scarce when compared to previous studies on wood. However, knowledge on bark structure and its variation within and between individuals of a species, as well as age-related trends, are important to assess bark's diagnostic value and to determine its potential uses (Roth, 1981). In this area, literature is also scarce (i.e. Trockenbrodt, 1994; Quilhó *et al.*, 2000; Jorge *et al.*, 2000; Babo *et al.*, 2010; Arslan & Güvenç, 2011; Tavares *et al.*, 2011). Only very limited information was published on the bark of the *Quercus* L. species. Bark anatomy of white and northern red oak was first described by Chang (1954). Whitmore (1962) compared the bark structure and surface pattern of mature trees of *Q. robur*. Howard (1977) observed the bark structure of 11 *Quercus* species. Trockenbrodt (1991, 1994, 1995) studied the qualitative and quantitative anatomy of *Q. robur* bark, and Sen *et al.* (2011a, 2011b) described in detail the bark of *Q. cerris* L. var. *cerris*. One exception is the research effort and detailed knowledge gathered on *Q. suber* bark, which is due to the economic importance of its cork component, as reviewed by Pereira (2007). The present study investigated the bark structure as well as between- and within-tree size variation of the sieve tube elements and secondary phloem fibres in *Q. faginea*. The results are the first to be published on the bark of this species, thereby also adding new information on the structural characteristics of *Quercus* spp. barks. We also think that this knowledge, besides being necessary to assess potential bark uses, has a role in the research on the sustainability of *Q. faginea* in its indigenous regions.
